Abstract - This paper presents a taxonomy allowing for the evaluation of task models with a focus on their applicability in model-based user interface development processes. It further supports the verification and improvement of existing task models, and provides developers with a decision-making aid for the selection of the most suitable task model for their development process or project. Furthermore, the taxonomy is applied on the Useware Markup Language 1.0. The results of the application are briefly described in this paper which led to the identification of substantial improvement potentials.

Keywords - Task model, Taxonomy, Useware Markup Language, Model-based User Interface Development, MBUID.

I. INTRODUCTION

The improvement of human-machine-interaction is an important field of research reaching far back into the past [22]. Yet, for almost two decades, graphical user interfaces have dominated their interaction in most cases. In the future, a broader range of paradigms will emerge, allowing for multi-modal interaction incorporating e.g., visual, acoustic, and haptic input and output in parallel [41]. But also the growing number of heterogeneous platforms and devices utilized complementarily (e.g., PC’s, smartphones, PDA) demand for the development of generic user interfaces for a plethora of target platforms; their consistency ensures their intuitive use and their users’ satisfaction [16].

To meet the consistency requirement, factors such as reusability, flexibility, and platform-independence play an important role for the development of user interfaces [7]. Further, the perseverative development effort for every single platform, single platform or even single use context solution is way too high, so that a model-based approach to the abstract development of user interfaces appears to be favorable [31].

The purpose of a model-based approach is to identify high-level models, which allow developers to specify and analyze interactive software applications from a more semantic oriented level rather than starting immediately to address the implementation level [18][36]. This allows them to concentrate on more important aspects without being immediately confused by many implementation details and then to have tools which, update the implementation in order to be consistent with high-level choices. Thus, by using models which capture semantically meaningful aspects, developers can more easily manage the increasing complexity of interactive applications and analyze them both during their development and when they have to be modified [28]. After having identified relevant abstractions for models, the next issue is specifying them through suitable languages that enable integration within development environments.

The pivotal model of a user-centric model-based development process is the task model [19]. Task models—developed during a user and use context analysis—are explicit representations of all user tasks [30]. Recently, several task modeling languages have been developed, which, differ, for example, in their degree of formalization, and their range of applications. To make the selection of a suitable task modeling language simpler, this paper introduces a task model taxonomy that enables all participants involved in an integrated MBUID (Model-based User Interface Development) process, to evaluate and compare task modeling languages.

The rest of this paper is structured as follows: Section II explains the proposed taxonomy for task models in detail. Section III gives a short introduction on the Useware Markup Language (useML) 1.0 followed by Section IV, which shows the application of the taxonomy on useML 1.0. The paper finishes with Section V, which gives a brief summary and an outlook on future activities.

II. THE TAXONOMY AND ITS CRITERIA

The proposed taxonomy focuses on the integration of task models into architectures for model-based development of user interfaces allowing for consistent and intuitive user interfaces for different modalities and platforms. For the evaluation of different task models, criteria describing relevant properties of these task models are needed. The criteria employed herein are based on initial work of [1] and [38], and are amended by additional criteria for task models with their application in MBUID. Following, the taxonomy and its criteria are described in detail.

A. Criterion 1: Mighteness

According to [26], a task model must help the developer to concentrate on tasks, activities, and actions. It must focus on the relevant aspects of task-oriented user interface specifications, without distracting by complexity. Yet, the granularity of the task definition is highly relevant. For the application of a task model in a MBUID process, the task model must comprise different levels of abstraction [15],
describing the whole bandwidth of interactions from abstract top-level tasks to concrete low-level actions. According to [34], it is commonly accepted that every person has her own mental representations (mental models) of task hierarchies. The hierarchical structure thereby constitutes the human’s intuitive approach to the solution of complex tasks and problems. Consequently, complex tasks are divided into less complex sub-tasks [11] until a level is reached where sub-tasks can be performed easily. Normally, task models are divided into two levels of abstraction. With abstract tasks the user is able to model more complex tasks, e.g., “Edit a file.” On the other hand a concrete task is an elemental or atomic task, e.g., “Enter a value.” Tasks should not be modeled too detailed, e.g., like in GOMS [8] at least at development time [10].

Tasks can also be modeled from different perspectives. A task model should differentiate at least between interactive user tasks and pure system tasks [4]. Pure system tasks encapsulate only tasks which, are executed by the computer (e.g., database queries). This differentiation is preferable, because it allows for deducting when to create a user interface for an interactive system, and when to let the system perform a task automatically.

A further aspect determining the mightiness of a task model is its degree of formalization. Oftentimes, task modeling relies on informal descriptions, e.g., use cases [10] or instructional text [9]. According to [27], however, these informal descriptions do rarely sufficiently specify the semantics of single operators as well as the concatenation of multiple operators (i.e., to model complex expressions). These task models therefore lack a formal basis [33], which impedes their seamless integration into the model-based development of user interfaces [25]. On the one hand, developers need a clear syntax for specifying user interfaces, and on the other hand, they need an expressive semantic. Furthermore, the specification of a task model should be checked for correctness, e.g., with a compiler. For these reasons a task model should rather employ at least semiformal semantics [24].

Using, for example, temporal operators (sometimes called qualitative temporal operators [14]) tasks can be put into clearly defined temporal orders [12]. The temporal order of sub-tasks is essential for task modeling [27] and opens up the road to a completely model-based development of user interfaces [15].

The attribution of optionality to tasks is another important feature of a task modeling language [1]. By itemizing a task as either optional or required, the automatic generation of appropriate user interfaces can be simplified. Similarly, the specification of cardinalities for tasks [26] allows for the automatic generation of loops and iterations. Several types of conditions can further specify when exactly tasks can, must, or should be performed. For example, logical [32] or temporal [14] conditions can be applied. Temporal conditions are also called quantitative temporal operators [14].

B. Criterion 2: Integratability

Due to the purpose of this taxonomy, the ease of a task model’s integration into a consistent (or even already given) development process, tool-chain or software architecture [15], is an important basic criterion. Therefore it is necessary to have a complete model-based view, e.g., to integrate different other models (dialog model, presentation model, etc.) in the development process [37]. Among others, the unambiguity of tasks is essential, because every task must be identified unequivocally, in order to match tasks with interaction objects, and to perform automatic model transformations [40].

C. Criterion 3: Communicability

Although task modeling languages were not explicitly developed for communicating within certain projects, they are suitable means for improving the communication within a development team, and towards the users [29]. Task models can be employed to formalize [1], evaluate [32], simulate [27] and interactively validate [3] user requirements. A task model should therefore be easily, preferably intuitively understandable, and a task modeling language must be easy to learn and interpret. Semi-formal notations have shown to be optimally communicable [24] in heterogeneous development teams.

D. Criterion 4: Editability

This criterion defines how easy or difficult the creation and manipulation of a task model appears to the developer [6]. In general, we can distinguish between plain-text descriptions like e.g., GOMS [8] and graphical notations like e.g., CTT [26] or GTA [38]. For the creation of task models, graphical notations are better utilizable than textual notations [12]. For example, graphical notations depict hierarchical structures more intuitively understandable. Here, one can further distinguish between top-down approaches like CTT, and left-right orders such as in GTA.

Although this fourth criterion is correlated to the third one (communicability), they put different emphases. For every graphical notation, obviously, dedicated task model editors are essential [27].

E. Criterion 5: Adaptability

This criterion quantifies how easily a task model can be adapted to new situations and domains of applications. This applies especially to the development of user interfaces for different platforms and modalities of interaction. The adaptability criterion is correlated to the mightiness criterion. Especially while using task models in the development process of user interfaces for ubiquitous computing applications [39], run-time adaptability is an important criterion [5], which must be considered.

F. Criterion 6: Extensibility

The extensibility of a task modeling language is correlated to its mightiness and adaptability. This criterion reveals the ease or complicacy of extending the semantics and the graphical notation of the task modeling language.
This criterion is highly significant, because it is commonly agreed that there is no universal task modeling language which, can be applied to all domains and use cases [6]. In general, semi-formal notations are more easily extendable than fully formal ones. Formal notations are usually based on well-founded mathematical theories which, rarely allow for fast extensions.

G. Criterion 7: Computability

Computability quantifies the degree of automatable processing of task models. This criterion evaluates, among others, the data management, including the use of well-established and open standards like XML as data storage format. Proprietary formats should be avoided, because they significantly hinder the automatic processing of task models.

H. Summary

Some of the criteria are partly correlated, e.g., the Editability criterion is aiming in the same direction as the Communicability criterion, but their focus in terms of usability is quite different (see Figure 1). The Adaptability criterion is correlating with the Mightiness and the Extensibility criteria. Furthermore the Extensibility criterion is correlated to the Mightiness criterion.

![Figure 1: Correlating criteria](image)

Table 1 shows all criteria and their possible values. All these possible values are more or less subjective. According to [6], the definition of more precise values is not possible, because there are no suitable metrics for value quantification.

IV. APPLICATION OF THE TAXONOMY ON USEML 1.0

In the following subsections the application of the taxonomy on useML 1.0 is briefly described.

A. Mightiness of useML 1.0

useML 1.0’s differentiation between use objects and five types of elementary use objects is sufficiently granular. With the classification of these elementary use objects types,
corresponding, abstract interaction objects can be determined [32]—which, the rougher differentiation of task types in the de facto standard CTT does not allow [2] [16] [35]. The use model or the useML 1.0 language, respectively, can be categorized as semi-formal. Though useML 1.0 is not based on formal mathematical fundamentals as e.g., Petri Nets [13], its structure is clearly defined by its XML schema. It allows, among others, for syntax and consistency checks which, ensure that only valid and correct use models can be created.

The use model by [32] focuses on the users’ tasks, while those tasks which, are fulfilled solely by the (computer) system, can’t be specified. Yet, for subsequently linking the use model to the application logic of a user interface, this task type is also required [2]. Querying a database might be such a pure system task which, however, might require that the query results are being presented to the user in an appropriate way. Pure system tasks can obviously be a part of a more complex, interactive action.

The hierarchical structure of the use model satisfies the Hierarchy sub-criterion of this taxonomy. Beside hierarchical structures, useML 1.0 also supports other structures, e.g., net structures. For the current useML 1.0 specification, however, no temporal operators were specified, which, constitutes a substantial limitation for the later integration of useML 1.0 into a fully model-based development process. In [32] Reuther himself admits that useML 1.0 does not possess temporal interdependencies between tasks. Task interdependencies must therefore be specified with other notations such as, e.g., activity diagrams. Such a semantic break, however, impedes developers in modeling the dynamics of a system, because they need to learn and use different notations and tools, whose results must then be consolidated manually. This further broadens the gap between Software- and Useware Engineering [41].

Although use models allow for specifying logical pre- and post-conditions, they don’t support quantitative temporal conditions. Also, they lack means for specifying invariant conditions that must be fulfilled at any time during the accomplishment of the respective task. Finally, the current useML 1.0 version cannot indicate that certain use objects or elementary use objects are optional or required ones, respectively. Although there is a similar attribute which, can be set to a project-specific, relative value (between 1 and 10, for example), this is not an adequate mean for formally representing the optionality of a task. Accordingly, there are no language elements in useML 1.0 that specify the cardinality (repetitiveness) of a task’s execution. The value of the Mightiness Criterion is based on the values of its sub criteria. Taking into account all the sub criteria, the value of the Mightiness criterion must be evaluated low.

B. Integratability of useML 1.0

Since no other models or modeling languages instead of use models or useML 1.0, respectively, have been applied and evaluated within projects pursuing the Useware Engineering Process, it is difficult to assess the applicability of use models into an integrated, MBUID architecture. Luyten mainly criticized the lack of dialog and presentation models complementing useML 1.0 [16]. Further, no unambiguous identifiers exist in useML 1.0 which, however, are required for linking (elementary) use objects to abstract or concrete interaction objects of a user interface—currently, use objects and elementary use objects can only be identified by their names that, of course, don’t need to be unique. UseML 1.0 must therefore be extended to arrange for unique identifiers for (elementary) use objects, before it can be integrated into a complex architecture comprising multiple models representing relevant perspectives on the interaction between humans and machines. Until then, the integratability of useML 1.0 into such a model-based architecture must be rated low.

C. Communicability of useML 1.0

Since Useware Engineering demands for an interdisciplinary, cooperative approach [21], use models and useML 1.0 should be easily learnable and understandable. Being an XML dialect, in principal, useML 1.0 models can be viewed and edited with simple text or XML editors. Yet, these representations are difficult to read, understand, and validate. Readers with little knowledge in XML will have problems handling use models this way. Much better readability is achieved with the web-browser-like presentation of use models in the useML-Viewer by Reuther [32] (see Figure 3).

![Figure 3: Excerpts of a use model as presented by the useML-Viewer](image)

This HTML-based viewer allows for easily reading, understanding, and evaluating use models even without any knowledge in XML. It also prints use models using the web browsers’ printer functions. However, the quality of the print is rather bad, among other reasons, because use models cannot be scaled to preferred paper sizes. Finally, the useML-Viewer can only display and print static use models, but does not provide means for interactive simulations or for the validation and evaluation of use models. Therefore, the communicability of useML 1.0 can only be rated medium.

D. Editability of useML 1.0

Though a simple editor may be sufficient for editing useML 1.0 models, XML editors are much more comfortable tools, especially those XML editors that run validity checks. Naturally, however, common versatile
XML editors from third party developers are not explicitly adapted to the specific needs of useML 1.0. Therefore, they cannot provide adequate means to simply and intuitively edit use models. The editability criterion of useML 1.0 must be rated low.

E. Adaptability of useML 1.0

useML 1.0 had been developed with the goal of supporting the systematic development of user interfaces for machines in the field of production automation. It focuses on the data acquisition and processing during the early phases of the Useware Engineering Process. Tasks, actions, and activities of a user are modeled in an abstract and platform-independent way. Thereby, the use model can be created already before the target platform has been specified. useML 1.0 provides for the incorporation of the final users and customers during the whole process, by allowing for the automatic generation of structure prototypes. The project-specific attributes (e.g., user groups, locations, device types) can be adjusted as needed, which means that useML 1.0 can be employed for a huge variety of modalities, platforms, user groups, and projects. Among others, useML 1.0 has already been applied successfully, e.g., in the domain of clinical information system development [17]. In conclusion the adaptability criterion can be rated high.

F. Extensibility of useML 1.0

The fact that useML 1.0 is not strictly based upon well-grounded mathematical theories, actually simplifies its enhancement and semantic extension. This can simply be done by modifying the XML schema of useML 1.0. In most cases, however, not even this is necessary, because useML 1.0 comprises a separate XML schema containing project-specific attributes (e.g., user groups, locations, device types) which, can easily be adjusted without changing the useML 1.0’s core schema. Since this allows for storing an unlimited number of use-case or domain-specific useML 1.0 schemes, the extensibility of useML 1.0 can be rated high.

G. Computability of useML 1.0

Since useML 1.0 is a XML dialect, use models can be further processed automatically. Employing dedicated transformations (e.g., XSLT style sheet transformations) prototypes can be generated directly from use models [21].

H. Summary of the evaluation of useML 1.0

The subsequently depicted table summarizes the evaluation of useML 1.0. Those criteria that were rated “No” or “Low”, highlight severe deficits of the language. Figure 4 visualizes the results of the evaluation in a radar chart that reveals these deficits: They identify starting points for the upcoming, and for future improvements of the useML 1.0.

V. CONCLUSION AND OUTLOOK

In this paper, a taxonomy for task models has been proposed, to simplify the selection of the most suitable task model for projects employing model-based development processes for user interfaces. Furthermore to show the feasibility of the task model taxonomy, it has been applied on useML 1.0. Also the application of the taxonomy on useML 1.0 showed the need for enhancing useML 1.0 semantically.

Currently we’re enhancing useML 1.0 in different aspects, according to the initial results of the application of the taxonomy. Additionally, we would like to improve the refinement of the criteria and apply this taxonomy to a selection of further task models, such as CTT [26] or AMBOSS [20] to proof the usefulness of this taxonomy.
