Abstract—In order to serve the changing needs of road traffic control, the road space and road structure surrounding an intersection have evolved into complex forms. The redesign or split of the trajectories though complex, can be accomplished by the application of methods for navigation, guidance and combination of expert knowledge of road traffic control of vehicles. A proposed innovative treatment for congested urban is the split intersection. It facilitates a smoother flow with less driver delay by reducing the number of vehicle signal phases. The success of converting to the split intersection is analyzed at times that minimizing delays. A Vehicle-to-Everything (V2X) traffic scenario is stablished and the experimental results confirm the cooperative Visible Light Communication (VLC) architecture showing that communication between connected bicycles and motor vehicles is optimized using a request/response concept. In this work, the communication between the infrastructures and the bicycles and motor vehicles, between vehicles and from the bicycles and motor vehicles to the infrastructures is performed through Visible Light Communication (VLC) using the street lamps and the traffic signaling to broadcast the information. Data is encoded, modulated and converted into light signals emitted by the transmitters. Tetra-chromatic white sources are used providing a different data channel for each chip. As receivers and decoders, SiC Wavelength Division Multiplexer (WDM) optical sensor, with light filtering properties, are used. The primary objective is to control the arrival of vehicles to an intersection and to schedule them to cross it at times that minimizes delays. A Vehicle-to-Everything (V2X) traffic scenario is stablished and bidirectional communication between the infrastructure and the vehicles is tested, using the VLC request/response concept.

Keywords: Vehicular Communication; Light Fidelity; Visible Light Communication; white LEDs; SiC photodetectors; OOK modulation scheme; Traffic control.

I. INTRODUCTION

The Visible Light Communication (VLC) holds special importance when compared to existing forms of wireless communications [1] [2]. VLC seems to be appropriate for providing wireless data exchange for automotive applications. Visible light represents a new communication opportunity for vehicular networking applications. The communication is performed through VLC using the street lamps and the traffic signaling to broadcast the information. An Intersection Manager (IM) can increase the throughput of the intersection by exchanging information with and directing incoming Connected Autonomous Vehicles [3][4][5]

Our goal is to increase the safety and throughput of traffic intersections using VLC connected cooperative driving [6][7]. Vehicular Communication Systems are a type of network in which vehicles and roadside units are the communicating nodes, providing each other with information, such as safety warnings and traffic information [8]. Communication between fixed locations and vehicles (Infrastructure-to-Vehicle, I2V) between vehicles (Vehicle-to-Vehicle, V2V), and between vehicles and fixed locations (Vehicle-to-Infrastructure, V2I) is essential to transfer information in real time. The I2V applications focus on utilizing the traffic related infrastructure, such as traffic light or streetlight to communicate useful information.

The proposed system is composed of several transmitters, i.e., the street lights and the traffic signals, which transmit map information and traffic messages required to the moving vehicles. Data is encoded, modulated and converted into light signals emitted by the transmitters. Then, this information is transferred to receivers installed in the vehicles. Every street light has their differentiable Identifications (IDs) for the generation of the visible light signal that transmits the map information through a Visible Light Transmitter module. Tetra-chromatic white sources are used providing a different data channel for each chip. Every vehicle is equipped with a receiver module for receiving the mapped information generated from the street. The receiver modules include a photodetector based on a tandem a-SiC:H/a-Si:H pin/pin light controlled filter [9][10][11] that multiplex the different optical channels, perform different filtering processes (amplification, switching, and wavelength conversion) and decode the encoded signals, recovering the transmitted information.
This paper is organized as follows: After a short introduction, in Section II, a two-way communication between vehicles and the traffic lights is implemented. The redesign of the trajectory is presented. Here, street lamps and traffic lights broadcast the information. The On-vehicle VLC receivers decode the messages and perform V2V distance measurements. In Section III, a V2X traffic scenario is proposed and characterized. A phasing traffic flow is developed as a Proof-of-Concept (PoC). The simulated results confirm that the redesign of the intersection and its management through the cooperative request/response VLC architecture allows to increase the safety and to decrease the trip delay. Finally in Section IV, the main conclusions are presented.

II. VEHICULAR COMMUNICATION USING VLC

In this section the vehicular communication is analyzed.

A. Redesign Concepts

The redesign of the traffic-actuated controller uses vehicle request/respond message information to generate phase durations appropriate to accommodate the demand on each cycle. Examples of the representation of a redesigned phasing diagram, a functional area with two-way-two-way intersection and a timing function configuration are presented in Figure 1. In Figure 1a, a phasing diagram is displayed. Each Timing Function (TF) controls only one movement represented by an arrow. Since two movements can proceed simultaneously without conflict as shown in Figure 1b, hence two of the timing functions will always have simultaneous control, as exemplified in Figure 1c. The problem that the traffic-actuated intersection manager has to solve is to allocate the reservations among a set of drivers in a way that a specific objective is maximized. Signal timing involves the determination of the appropriate cycle length and apportionment of time among competing movements and phases. The timing apportionment is constrained by minimum “green” times that must be imposed to provide pedestrians to cross and to ensure that motorist expectancy is not violated.

The use of both navigation and lane control signs to communicate lane restrictions is demanding. Downstream from that location (request distance in Figure 1b), lane restrictions should be obeyed. Vehicles may receive their requirements (*e.g.*, whether they will turn left or continue straight and turn right) or the need to interact with a traffic controller at a nearby crossroad (message distance in Figure 1b). In the sequence, a traffic message coming from a transmitter nearby the crossroad will inform the drivers of the location of their destination (*i.e.*, the intended intersection exit leg).

B. V2X communication scenario .

A V2X (I2V2V2I2V) communication link, in a light traffic controlled crossroad, was simulated. The crossroad link is displayed in Figure 2. In the PoC, was assumed that the crossroad in an orthogonal configuration is located in the interception of line 2 with column 3, and the emitters at the nodes along the roadside.

To build the I2V it is proposed a simplified cluster of unit square cells in an orthogonal topology that fills all the service area [13]. To realize both the communication and the street illumination, white light tetra-chromatic sources are used providing a different data channel for each chip. At each node, only one chip of the LED is modulated for data transmission, the Red (R: 626 nm), the Green (G: 530 nm), the Blue (B: 470 nm) or the Violet (V) while the others provide constant current for white perception. Thus, each transmitter, \( X_{i,j} \), carries its own color, \( X \), (RGB) as well as its horizontal and vertical ID position in the surrounding network \((i,j)\).

The VLC photosensitive receiver is a double pin/pin photodetector based on a tandem heterostructure, \( p-i'(a - SiC:H)-n/p-i(a-Si:H)-n \). [12] [13]. To receive the I2V
information from several transmitters, the receiver must be located at the overlap of the circles that set the transmission range of each transmitter.

The nine possible overlaps are displayed in Figure 2a for each unit square cell. When a probe vehicle enters the streetlight’s capture range, the receiver replies to the light signal, and assigns an unique ID and the traffic message [14]. In Figure 2b, we propose a draft of a mesh cellular hybrid structure to create a gateway-less system without any external gateways needed. We propose this network configuration since it is wireless and ad-hoc. It spans all devices, is wire free, demonstrates resiliency to physical obstructions and adapts to changes in the transmission medium. Therefore, a mesh network is a good fit because it dynamically reconfigures itself and grows to the size of any installation. Is also a secure and trustworthy network [15]. As illustrated in Figure 2b, the street lights, in this architecture, are equipped with one of two types of nodes: A “mesh” controller that connects with other nodes in its vicinity (solid arrows). These controllers can forward messages to the vehicles (I2V) in the mesh, effectively acting like routers nodes in the network. The “mesh/ cellular” hybrid controller (dash arrows), is also equipped with a modem providing IP base connectivity to the Intersection Manager services (IM). These nodes act as border-router and can be used for edge computing. Under this architecture, the short-range mesh network purpose is twofold: enable edge computing and device-to-cloud communication, by ensuring a secure communication from a street light controller to the edge computer or datacenter, through a neighbor traffic light controller with an active cellular connection; and enable peer-to-peer communication, to exchange information between V-VLC ready connected cars.

Four traffic flows were considered: One from West (W) with three vehicles (“a”, “c”, “d”) approaching the crossroad, Vehicle a with straight movement and Vehicle c and Vehicle d with left turn only. In the second flow, Vehicle b from East (E), approaches the intersection with left turn only. In the third flow, Vehicle e, oncoming from South (S), has e right-turn approach. Finally, in the fourth flow, Vehicle f, coming from North, goes straight. Using the I2V communication, each street lamp (transmitter) sends a message, which is received and processed by a SiC receiver, located at the vehicle’s rooftop. Using the headlights as transmitters, the information is resent to a leader vehicle (V2V) or, depending on the predefined occupied lane, a “request” message to go forward or turn right (right lane) or to turn left (left lane) is sent directly to a crossroad receiver (V2I), at the traffic light, interconnected to a local manager that feeds one or more signal heads. For crossroad coordination, a emitting local controller located at the light signal, sends a “response” message to the intersection approaching vehicles. In the following, bidirectional communication is stablished (V2I2V).

To build the V2V system, the follower sends the message that is received by the leader and can be retransmitted to the next car [16][17] or to the infrastructure. The leader vehicle receives infers the drive distance and the
relative speed between them [18]. This information can be directed to the next car (V2V) or to an infrastructure (V2I).

For the intersection manager crossing coordination, the vehicle and the intersection manager exchange information through two specific types of messages, “request” (V2I) and “response” (I2V). Inside the request distance, an approach “request” is sent, using as emitter the headlights. To receive the “requests”, two different receivers are located at the same traffic light, facing the cross roads (local controller of the traffic light). The “request” contains all the information that is necessary for a vehicle’s space-time reservation for its intersection crossing. Intersection manager uses this information to convert it in a sequence of timed rectangular spaces that each assigned vehicle needs to occupy the intersection. An intersection manager’s acknowledgement is sent from the traffic signal over the facing receiver to the in car application of the head vehicle. The response includes both the infrastructure and the vehicle identifications and the “confirmed vehicle” message. Once the response is received (message distance in Figure 1b), the vehicle is required to follow the occupancy trajectories (footprint regions, Figure 2) provided by the intersection manager. If a request has any potential risk of collision with all other vehicles that have already been approved to cross the intersection, the control manager only sends back to the vehicle (V2I) the “response” after the risk of conflict is exceeded.

The graphical representation of the simultaneous localization and mapping problem, for the V2X communication link, is displayed in Figure 2c. Here, using the I2V communication, each street lamp (transmitter) sends a message, which is received and processed by a SiC receiver, located at the vehicle’s rooftop. Using the headlights as transmitters, the information is resent to a leader vehicle (V2V) [19] [20] or, depending on the predefined occupied lane, a “request” message to go forward or turn right (right lane) or to turn left (left lane) is sent directly to a crossroad receiver (V2I), at the traffic light, interconnected to a local manager that feeds one or more signal heads. This information can be directed to the next car (V2V) or to an infrastructure (V2I). For crossroad coordination, an emitting local controller located at the light signal, send a “response” message to the intersection approaching vehicles. In the following, bidirectional communication is stablished (V2I2V).

C. Coding/decoding Techniques

To encode the messages an on-off keying (OOK) modulation scheme was used. The codification of the optical signals is synchronized and includes the information related to the ID position of the transmitters and the message to broadcast. We have considered a 32 bits codification as described in Figure 3.

Each frame is divided into three or four blocks depending on the kind of transmitter: street lamps, headlamps (Figure 3a) or traffic light (Figure 3b). We assigned the first block to the synchronization (SYNC) in a [10101] pattern and the last one to the message to transmit (Payload Data). A stop bit is used at the end of each frame. Thus, R3,2, G3,1, and V2,1 are the transmitted node packets, in a time slot by the headlamps. In Figure 3b, the second block (INFO) in a pattern [000000] means that a response message is being sent by the controller manager. Here, the signal controller responds to the request of the vehicle located in position # 8 (R3,2, G3,1, and V2,1) at the request time (request distance). This response is received in the unit cell adjacent to the crossroad (message distance, Figure 1b) that shares a common node (R3,2) with the request distance (see Figure 3).

![Figure 3](image)

Figure 3. Frame structure representations. a) Codification used to drive the headlamps of a vehicle in a request message from footprint #8. R3,2, G3,1, and V2,1 are the transmitted node packet, in a time slot. b) Encoded message response of the controller to the request message of the vehicle in position #8 (R3,2, G3,1, and V2,1).

In Figure 4, a MUX signal due to the joint transmission of four R, G, B and V optical signals, in a data frame, is displayed. The bit sequence (on the top of the figure) was chosen to allow all the on/off sixteen possible combinations of the four input channels (24).

Results show that the code signal presents as much separated levels as the on/off possible combinations of the input channels, allowing decoding the transmitted information [9]. All the levels (d0-d1) are pointed out at the correspondent levels, and displayed as horizontal dotted lines. In the right hand side, the match between MUX levels and the 4 bits binary code assigned to each level is shown. To exemplify of the decoding technique, the signal transmitted in Figure 3a in the same frame of time, is also added (dotted curve).
Hence, the signal can be decoded by assigning each output level \((d_0, d_1, \ldots)\) to a 4-digit binary code \([X_R, X_G, X_B, X_V]\), with \(X=1\) if the channel is on and \(X=0\) if it is off.

III. RESULTS

Main results are presented and discussed.

A. Led assisted navigation

As a PoC, performed in the lab, a navigation data bit transition was tested by moving the receiver along known pattern path as shown in Figure 5.

Figure 5. Normalized MUX signals acquired by a receiver at the crossroad, in positions #1, #2, #4, #6 or #8. On the top the transmitted channels packets \([R, G, B, V]\) are decoded.

Figure 5 displays the MUX signals received when Vehicle \(a\) enters the crossroad in position \#8 \((t_1)\) and it goes straight to position \#2 \((t_2)\) (Phase1, TF1), while vehicle \(c\) turn left, moving across position \#1 (Phase2, TF2). Results show that, as the receiver moves between generated point regions, the received information pattern changes. The vehicle speed can be calculated by measuring the actual travelled distance overtime, using the ID’s transmitters tracking. Between two consecutive data sets, there is a navigation data bit transition (channel is missing or added). It was observed that when the receiver moves from \#8 to \#2 one ID channels was lost \((B_{s,3})\) and one are added \((V_{s,3})\). Here, the 4-binary bit code has changed from \([1101]\) to \([1110]\) while Vehicle \(c\) and \(d\) change theirs from \([1111]\) to \([0011]\) and Vehicle \(b\) to \([1100]\). The receivers compute the geographical position in the successive instants (path) and infer the vehicle’s speed. In the following, this data will be transmitted to another leader vehicle through the V2V communication or to control manager at the traffic light through V2I.

B. Cooperative system

To model the worst-case scenario, vehicles approaching the intersection from different flows are assumed to have a conflicting trajectory (Figure 2). Two instants are considered for each vehicle, the request time \((t)\) and the response time \((t')\). All the requests contain vehicle positions and approach speeds. If a follower exists (Vehicle \(d\)), the request message from its leader includes the position and speed previously received by V2V. This information alerts the controller to a later request message (V2I), confirmed by the follow vehicle. In the PoC we have assumed that \(t_a < t_f < t_b\), and \(t_a < t_b < t_c\).

Figure 6. MUX signals and the assigned decoded messages (at the top of the figure) from vehicles \(b, e\) and \(f\) at different request and response times \((t2V)\).

As an example, in Figure 6, the I2V MUX signals received and decode (on the top of the figure) by the receivers of the vehicles \(b, e\) and \(f\) are also displayed at request \((t_c)\) and \((t'_b\) and \(t'_f)\) response times. In the right side,
the received channels for each vehicle are identified by its 4-digit binary codes and associated positions in the unit cel.

After decoding we have assigned position #4 (R_{1,4}, G_{4,4}, V_{4,3}) for Vehicle e, position #1 (R_{3,4}, G_{3,5}, B_{2,4}, V_{2,3}) for Vehicle b and position #8 (R_{1,4}, G_{1,3}, V_{2,3}) to Vehicle f respectively at theirs request and response times t_e, t_b and t_f. Here, t_e < t_f.

C. Traffic Signal Phasing in a V2X Communication

A phasing diagram and a timing function configuration were presented in Figure 1, for functional areas with two-way-two-way intersection. A traffic scenario was simulated (Figure 2) using the new concept of VLC request/response messages. A brief look into the process of timing traffic signals is given in Figure 7.

Redesign traffic-actuated controller uses a, b, c, d, e and f vehicles requesting and responding message information to generate phase durations appropriate to accommodate the demand on each cycle. Each driving vehicle is assigned an individualised time to request (t) and access (t') the intersection. The exclusive pedestrian stage, “Walk” interval begins at the end of Phase 5. (Figure 1).

Figure 7 Requested phasing of traffic flows: pedestrian phase, Phase 1 (W straight flow), Phase 2 (W straight and left flows), Phase 3 (W straight and left flows). t_{xy} is the request time from the Vehicle x and t_{xy} the correspondent response time from the manage controller.

A first-come-first-serve approach could be realized by accelerating or decelerating the vehicles such that they arrive at the intersection when gaps in the conflicting traffic flows and pedestrians have been created. However, a one-by-one service policy at high vehicle arrival rates is not efficient. From the capacity point of view, it is more efficient, if Vehicle c is given access at t'_c before Vehicle b, at t_b to the intersection and Vehicle d is given access at t'_d before Vehicle e, at t_e, then, forming a west left turn of set of vehicles (platoon) before giving way to the fourth phase (north and south conflicting flows), as stated in Figure 7.

The speed of Vehicle e was reduced, keeping a safe distance between Vehicle e and Vehicle d.

IV. Conclusions

This paper presents a new concept of request/response for the redesign and management of a trajectory in a two-way-two-way traffic lights controlled crossroad, using VLC between connected cars. The connected vehicles receive information from the network (I2V), interact with each other (V2V) and also with the infrastructure (V2I), using the request redesign distance concept. In parallel, a control manager coordinates the crossroad and interacts with the vehicles (I2V) using the response redesign distance concept. A simulated traffic scenario was presented and a generic model of cooperative transmission for vehicular communication services was established. As a PoC, a phasing of traffic flows is suggested. The simulated/experimental results confirmed that the proposed cooperative VLC architecture is suitable for the intended applications. The introduction of VLC between connected vehicles and the surrounding infrastructure allows the direct monitoring of relative speed thresholds and inter-vehicle spacing.

In order to evolve towards real implementation, the performance of such systems still needs improvement, namely the distance between conflicting vehicles along with the trajectories of other opposing vehicles should also be monitored and optimized. As further work, the research team plans to finalize the embedded application, for experimenting in several road configurations with either static or moving vehicles.
